Why Parallel ?

- P is the portion of the program that benefits from parallelization
- Amdahl's Law (1967)
 - Maximum speedup *sAmdahl* by *N* processors
 - Largest impact of parallelization with small N and / or small (1-P)
 - Speedup by increasing *N* is limited
- Gustafson's Law (1988)
 - Maximum speedup *s*_{Gustafson} by *N* processors
 - Assumption: Problem size grows with *N*, so the inheritly serial portion becomes smaller as proportion to the overall problem
 - With neglection of the parallelization overhead, speedup can grow as *N*

$$Amdahl = \frac{1}{(1-P) + \frac{P}{N}}$$

S

S

$$Gustafson = \frac{(1-P)_N + N * P_N}{(1-P)_N + P_N}$$

$$= (1-P)_N + N * P_N$$

(1-P)+P

Amdahl's Law

Joseph Jájá

Parallel Algorithms and Design Patterns

- Vast body of knowledge in books and scientific publications
- Typically discussion based on abstract machine model (e.g. PRAM), to allow theoretical complexity analysis
- Rule of thumb: Somebody else is smarter than you reuse !!

Distributed Algorithms [Lynch]

- Originally only for concurrent algorithms across geographically distributed processors
- Attributes
 - IPC method (shared memory, point-to-point, broadcast, RPC)
 - Timing model (synchronous, partially synchronous, asynchronous)
 - Fault model
 - Problem domain
- Have to deal with uncertainties
 - Unknown number of processors, unknown network topology, inputs at different locations, non-synchronized code execution, processor nondeterminism, uncertain message delivery times, unknown message ordering, processor and communication failures, ...

Designing Parallel Algorithms [Breshears]

- Parallel solution must keep sequential consistency property
- "Mentally simulate" the execution of parallel streams on suspected parts of the sequential application
- Amount of computation per parallel task must offset the overhead that is always introduced by moving from serial to parallel code
- Granularity: Amount of computation done before synchronization is needed
 - Fine-grained granularity overhead vs. coarse-grained granularity concurrency
 - Iterative approach of finding the right granularity
 - Decision might be only correct only for the execution host under test
- Execution order dependency vs. data dependency

Designing Parallel Algorithms [Foster]

- Translate problem specification into an algorithm achieving concurrency, scalability, and locality
- Best parallel solution typically differs massively from the sequential version
- Four distinct stages of a methodological approach
 - Search for concurrency and scalability:
 - 1) **Partitioning** decompose computation and data into small tasks
 - 2) **Communication** define necessary coordination of task execution
 - Search for locality and other performance-related issues:
 - 3) **Agglomeration** consider performance and implementation costs
 - 4) **Mapping** maximize processor utilization, minimize communication
- Might require backtracking or parallel investigation of steps

 7

Partitioning Step

- Expose opportunities for parallel execution fine-grained decomposition
- Good partition keeps computation and data together
 - First deal with data partitioning *domain / data decomposition*
 - First deal with computation partitioning functional / task decomposition
 - Complementary approaches, can lead to different algorithm versions
 - Reveal hidden structures of the algorithm that have potential through complementary views on the problem
- Avoid replication of either computation or data, can be revised later to reduce communication overhead
- Step results in multiple candidate solutions

Partitioning - Decomposition Types

- Domain Decomposition
 - Define small data fragments, then specify computation for them
 - Different phases of computation on the same data are handled separately
 - Rule of thumb: First focus on large or frequently used data structures
- Functional Decomposition
 - Split up computation into disjoint tasks, ignore the data accessed for the moment
 - Example: Producer / consumer
- With significant data overlap, domain decomposition is more appropriate ParProg | Algorithms

Partitioning Strategies [Breshears]

- Loop parallelization
 - Reason about code behavior when loop would be executed backwards strong indicator for independent iterations
- Produce at least as many tasks as there will be threads / cores
 - But: Might be more effective to use only fraction of the cores (granularity)
 - Computation part must pay-off with respect to parallelization overhead
- Avoid synchronization, since it adds up as overhead to serial execution time
- Patterns for data decomposition: by element, by row, by column group, by block
 - Influenced by surface-to-volume ratio

Partitioning - Checklist

- Checklist for resulting partitioning scheme
 - Order of magnitude more tasks than processors ?
 -> Keeps flexibility for next steps
 - Avoidance of redundant computation and storage requirements ?
 -> Scalability for large problem sizes
 - Tasks of comparable size ?
 -> Goal to allocate equal work to processors
 - Does number of tasks scale with the problem size ?
 Algorithm should be able to solve larger tasks with more processors
- Resolve bad partitioning by estimating performance behavior, and eventually reformulating the problem

Communication Step

- Specify links between data consumers and data producers
- Specify kind and number of messages on these links
- Domain decomposition problems might have tricky communication infrastructures, due to data dependencies
- Communication in functional decomposition problems can easily be modeled from the data flow between the tasks
- Categorization of communication patterns
 - Local communication (few neighbors) vs. global communication
 - Structured communication (e.g. tree) vs. unstructured communication
 - Static vs. dynamic communication structure
 - Synchronous vs. asynchronous communication

ParProg | Algorithms

Communication - Hints

- Distribute computation and communication, don't centralize algorithm
 - Bad example: Central manager for parallel reduction
 - *Divide-and-conquer* helps as mental model to identify concurrency
- Unstructured communication is hard to agglomerate, better avoid it
- Checklist for communication design
 - Do all tasks perform the same amount of communication ?
 -> Distribute or replicate communication hot spots
 - Does each task performs only local communication ?
 - Can communication happen concurrently ?
 - Can computation happen concurrently ?

Ghost Cells

- Domain decomposition might lead to chunks that demand data from each other for their computation
 - Solution 1: Copy necessary portion of data (,ghost cells')
 - Feasible if no synchronization is needed after update
 - Data amount and frequency of update influences resulting overhead and efficiency
 - Additional memory consumption
 - Solution 2: Access relevant data ,remotely' as needed
 - Delays thread coordination until the data is really needed
 - Correctness ("old" data vs. "new" data) must be considered on parallel progress

Agglomeration Step

- Algorithm so far is correct, but not specialized for some execution environment
- Check again partitioning and communication decisions
 - Agglomerate tasks for more efficient execution on some machine
 - Replicate data and / or computation for efficiency reasons
- Resulting number of tasks can still be greater than the number of processors
- Three conflicting guiding decisions
 - Reduce communication costs by *coarser granularity* of computation and communication
 - Preserve flexibility with respect to later mapping decisions
 - Reduce software engineering costs (serial -> parallel version)

Agglomeration [Foster]

Agglomeration - Granularity vs. Flexibility

- Reduce communication costs by coarser granularity
 - Sending less data
 - Sending fewer messages (per-message initialization costs)
 - Agglomerate tasks, especially if they cannot run concurrently anyway
 - Reduces also task creation costs
 - Replicate computation to avoid communication (helps also with reliability)
- Preserve flexibility
 - Flexible large number of tasks still prerequisite for scalability
- Define granularity as compile-time or run-time parameter

Agglomeration - Checklist

- Communication costs reduced by increasing locality ?
- Does replicated computation outweighs its costs in all cases ?
- Does data replication restrict the range of problem sizes / processor counts ?
- Does the larger tasks still have similar computation / communication costs ?
- Does the larger tasks still act with sufficient concurrency ?
- Does the number of tasks still scale with the problem size ?
- How much can the task count decrease, without disturbing load balancing, scalability, or engineering costs ?
- Is the transition to parallel code worth the engineering costs ?

Mapping Step

- Only relevant for distributed systems, since shared memory systems typically perform automatic task scheduling
- Minimize execution time by
 - Place concurrent tasks on different nodes
 - Place tasks with heavy communication on the same node
- Conflicting strategies, additionally restricted by resource limits
 - In general, NP-complete bin packing problem
- Set of sophisticated (dynamic) heuristics for *load balancing*
 - Preference for local algorithms that do not need global scheduling state

Surface-To-Volume Effect [Foster, Breshears]

- Communication requirements of a task are proportional to the surface of the data part it operates upon - amount of ,borders' on the data
- **Computational** requirements of a task are proportional to the **volume** of the data part it operates upon granularity of decomposition
- Communication / computation ratio decreases for increasing data size per task
- Better to have coarse granularity by agglomerating tasks in all dimensions
 - For given volume (computation), the surface area (communication) then goes down -> good

	1 ∭	Surface area in total volume re	ncreases while mains constant	
Total surface area (height × width × number of sides × number of boxes)	6	150	750	
Total volume (height × width × length × number of boxes)	1	125	125	
Surface-to-volume ratio (surface area / volume)	6	1.2	6	

Surface-to-Volume Effect [Foster]

- Computation on 8x8 grid
- (a): 64 tasks, one point each
 - 64x4=256 communications
 - 256 data values are transferred
- (b): 4 tasks, 16 points each
 - 4x4=16 communications
 - 16x4=64 data values are transferred
